

Application Architecture

So to handle multiple req we may require

↑ CPU
↑ RAM
↑ Disk (Vertical Scale)

* Vertical Scaling - take a single server / computer and then making it better by adding better server or say adding a block to itself

* Horizontal Scaling - Since each computer has a limitation HS means take our server and make more copies of it (benefit is multiple request can be handled at the same time)

Alert Service - can help send push notification to developer if any resource / metrics is going below a threshold
